### Introduction

#### 1.1 Definitions

A graph G = (V, E) is a set V of vertices and a set E of unordered pairs of distinct vertices, called edges. Write vw or  $\{v, w\}$  for the edge joining v and w, and say that v and w are **neighbours** or that they are adjacent.

In these notes, unless otherwise stated, graphs are:

- finite:  $|V| \in \mathbb{N}$ .
- labelled: vertices are distinguishable, usually  $V = [n] := \{1, 2, ..., n\}$  for some  $n \in \mathbb{N}$ .
- undirected: edges are unordered pairs of vertices.
- simple: no loops  $\{v, v\}$  or multiple edges (since E is not a multiset).

A graph G with vertex set  $\{v_1, \ldots, v_n\}$  has adjacency matrix  $A(G) = (a_{ij})$  where

$$a_{ij} = \begin{cases} 1 & \text{if } v_i v_j \in E, \\ 0 & \text{otherwise.} \end{cases}$$

A(G) is a **symmetric**  $n \times n$  0-1 matrix with zero diagonal.

The **trivial graph** has at most one vertex. Hence it has no edges.

A **subgraph** of a graph G = (V, E) is a graph H = (W, F) such that  $W \subseteq V$  and  $F \subseteq E$ .

We say that H is an **induced subgraph** if for all  $v, w \in W$  if  $vw \in E(G)$  then  $vw \in E(H)$ . Write H = G[W], and say that H is the subgraph of G induced by the vertex set W.

The number of **vertices** of G, written |G| = |V(G)|, is called the *order* of G. The number of **edges** of G, sometimes written |G| = |E(G)|, is called the *size* of G.

Two graphs G = (V, E) and H = (W, F) are **isomorphic** if there exists a bijection  $\phi : V \to W$  such that  $\phi(v)\phi(w) \in F$  if and only if  $vw \in E$ . The map  $\phi$  is called a graph isomorphism or isomorphism.

#### 1.2 The Degree of a Vertex

If  $v \in e$  where v is a vertex and e is an edge, then we say that e is incident with v. The **degree**  $d_G(v)$  of vertex v in a graph G is the number of edges of G which are incident with v. A vertex of degree 0 is an isolated vertex.

Let  $N_G(v)$  be the set of all **neighbours** of v in G, then d(v) = |N(v)|.

**Lemma 1.2.1** (The Handshaking Lemma). In any graph, G = (V, E),

$$\sum_{v \in V} d(v) = 2|E|.$$

Let  $\delta(G) = \min_{v \in V} d(v)$  be the minimum degree in G, and  $\Delta(G) = \max_{v \in V} d(v)$  be the maximum degree in G.

#### 1.2.1 Some Special Graphs

A graph is k-partite if there exists a partition of its vertex set

$$V = V_1 \cup V_2 \cup \cdots V_k$$

into k nonempty disjoint subsets (parts) such that there are no edges between vertices in the same part.

The **complete graph** on r vertices, denoted  $K_r$ , has all  $\binom{r}{2}$  edges present. The **complete bipartite** graph  $K_r$ , s has r vertices in one part of the vertex bipartition, s vertices in the other, and all rs present.

A graph is **regular** if every vertex has the same degree. If every vertex of a graph has degree d then we say that the graph is d-regular.

The **complement** of a graph G is the graph  $\bar{G} = (V, \bar{E})$  where  $vw \in \bar{E}$  if and only if  $vw \notin E$ . Note that  $\bar{K}_n$  is the graph with n vertices and no edges.

If G = (V, E) and  $X \subset V$  then G - X denotes the graph obtained from G by deleting all vertices in X and all edges which are incident with vertices in X. If  $F \subseteq E$  then G - F denotes the graph (V, E - F) obtained from G by deleting the edges in F.

#### 1.3 Paths and Cycles

A walk in the graph G is a sequence of vertices  $v_0v_1v_2\cdots v_k$  such that  $v_iv_{i+1}\in E$  for  $i=0,1,\ldots,k-1$ . The length of this walk is k. The walk is closed if  $v_0=v_k$ .

An **Euler tour** is a *closed walk* in a graph which uses every edge precisely once. A graph is Eulerian if it has an Euler tour.

**Theorem 1.3.1** (Euler, 1736). A connected graph is Eulerian if and only if every vertex has even degree.

A walk is a **path** if it does not visit any vertex more than once. A path is a sequence of *disinct* vertices, with subsequence vertices joined by an edge. A path  $v_0v_1...v_k$  with k edges is called a k-path and has length k.

If  $k \geq 3$  and  $P = v_0 v_1 \cdots v_{k-1}$  is a path of length k-1 then  $C = P + v_0 v_{k-1}$  is a **cycle** of length k, also called a k-cycle. It is a closed walk which visits no internal vertex more than once.

An edge which joins two vertices of a cycle C, but which is not an edge of C, is called a **chord**. An **induced cycle** is a cycle which has no chords.

**Proposition 1.3.2.** Every graph G contains a path of length  $\delta(G)$  and a cycle of length at least  $\delta(G) + 1$ , if  $\delta(G) \geq 2$ .

**Proof.** Let  $P = x_0 x_1 \dots x_k$  be the longest path in G. By maximality of P, all neighbours of  $x_k$  lie on P. Hence  $\delta(G) \leq d(x_k) \leq k = |\{x_0, x_1, \dots, x_{k-1}\}|$ , which proves the first statement. Let  $x_i$  be the smallest-indexed neighbour of  $x_k$  in P. Then  $C = x_k x_i x_{i+1} \dots x_{k-1} x_k$  is a cycle of length  $\geq \delta(G) + 1$  because C contains  $d(x_k) \geq \delta(G)$  neighbours of  $x_k$  as well as  $x_k$ .

The minimum length of a cycle in G is the girth of G, denoted by q(G).

Given  $x, y \in V$ , let  $d_G(x, y)$  be the length of a shortest path from x to y in G, called the **distance** from x to y in G. Set  $d_G(x, y) = \infty$  if no such path exists.

We say that G is **connected** if  $d_G(x, y)$  is finite for all  $x, y \in V$ .

Let the **diameter** of G be  $diam(G) = \max_{x,y \in V} d_G(x,y)$ .

**Proposition 1.3.3.** Every graph G which contains a cycle satisfies  $g(G) \leq 2 \operatorname{diam}(G) + 1$ .

**Proof.** Let C be a shortst cycle in G, so |C| = g(G). For a contradiction, assume  $g(G) \ge 2 \operatorname{diam}(G) + 2$ .

Choose vertices x, y on C with  $d_C(x, y) \ge \operatorname{diam}(G) + 1$ . In G the distance  $d_G(x, y)$  is strictly smaller, so any shortest path P from x to y in G is not a subgraph of C. But using P together with the shorter arc of C from x to y gives a closed walk of length < |C|. This closed walk contains a shorter cycle than C which is a contradiction.

### 1.4 Connectivity

A maximal connected subgraph of G is called a **component** (or **connected component**) of G.

**Proposition 1.4.1.** The vertices of a connected graph can be labelled  $v_1, v_2, \ldots, v_n$  such that  $G_n = G$  and  $G_i = G[v_1, \ldots, v_i]$  is connected for all i.

**Proof.** Choose  $v_1$  arbitrarily. Now suppose that we have labelled  $v_1, \ldots, v_i$  such that  $G_j = G[v_1, \ldots, v_j]$  is connected for all  $j = 1, \ldots, i$ .

If i < n then  $G_i \neq G$ , so there exists some  $v_j \in \{v_1, \ldots, v_i\}$  with a  $w \notin \{v_1, \ldots, v_i\}$  in G. (Otherwise  $G_i \neq G$  is a component of G, impossible as G is connected.) Let  $v_{i+1} = w$ , then  $G_{i+1} = G[v_1, \ldots, v_{i+1}]$  is connected. This completes the proof, by induction.

Let  $A, B \subseteq V$  be sets of vertices. An (A, B)-path in G is a path  $P = x_0 x_1 \cdots x_k$  such that

$$P \cap A = \{x_0\}, \quad P \cap B = \{x_k\}.$$

Let  $A, B \subseteq V$  and let  $X \subseteq V \cup E$  be a set of vertices and edges. We say that X separates A and B in G if every (A, B)-path in G contains a vertex or edge from X.

Note that we do not assume that A and B are disjoint and if X separates A and B then  $A \cap B \subseteq X$ . We say that X separates two vertices a, b if  $a, b \notin X$  and X separates the sets  $\{a\}, \{b\}$ .

More generally, we say that X separates G, and call X a **separating set** for G, if X separates two vertices of G. That is, X separates G if there exist distinct vertices  $a, b \notin X$  such that X separates a and b.

If  $X = \{x\}$  is a separating set for G, where  $x \in V$ , then we say that x is a **cut vertex**.

If  $e \in E$  and G - e has more components than G then e is a **bridge**.

The unordered pair (A, B) is a **separation** of G if  $A \cup B = V$  and G has no edge between A - B and B - A. The second conditions says that  $A \cap B$  separates A from B in G. If both A - B and B - A are nonempty then the separation is **proper**. The order of the separation is  $|A \cap B|$ .

**Definition.** Let  $k \in \mathbb{N}$ . The graph G is **k-connected** if |G| > k and G - X is connected for all subsets  $X \subseteq V$  with |X| < k.

The **connectivity**  $\kappa(G)$  of G is defined by

$$\kappa(G) = \max\{k : G \text{ is } k\text{-connected}\}.$$

So,  $\kappa(G) = 0$  iff G is trivial or G is disconnected. Also,  $\kappa(K_n) = n - 1$  for all positive integers n.

**Definition.** Let  $\ell \in \mathbb{N}$  and let G be a graph with  $|G| \geq 2$ . If G - F is connected for all  $F \subseteq E$  with  $|F| < \ell$  then G is  $\ell$ -edge-connected.

The **edge connectivity**  $\lambda(G)$  is defined by

$$\lambda(G) = \max\{\ell : G \text{ is } \ell\text{-edge-connected}\}.$$

**Proposition 1.4.2.** If  $|G| \ge 2$  then  $\kappa(G) \le \lambda(G) \le \delta(G)$ .

**Theorem 1.4.3** (Mader, 1973). Let k be a positive integer. Every graph G with average degree at least 4k has a (k+1)-connected subgraph H with

$$\frac{|E(H)|}{|V(H)|} > \frac{|E(G)|}{|V(G)|} - k.$$

**Proof.** We write |G| instead of |V(G)|. Let  $\gamma = \frac{|E(G)|}{|G|} \ge 2k$ . Consider subgraphs G' of G which satisfy:

$$|G'| \ge 2k$$
 and  $|E(G')| > \gamma(|G'| - k)$ . (1.1)

such graphs G' exists as G satisfies 1.1. (Average degree of G is  $\frac{2|E(G)|}{|G|} \geq 4k$ , so

$$|G| \ge 4k$$
 and  $\gamma(|G| - k) = |E(G)| \frac{(|G| - k)}{|G|} < |E(G)|$ .)

Now let H be a subgraph of G of smallest order which satisfies 1.1. We continue the proof by proving three claims.

Claim 1. If G' satisfies 1.1 then |G'| > 2k.

**Proof.** If G' satisfies 1.1 and |G'| = 2k then  $|E(G')| > \gamma(|G'| - k) \ge 2k^2 > {|G'| \choose 2}$ , contradiction.

Claim 2.  $S(H) > \gamma$ .

**Proof.** For a contradiction, suppose that  $S(H) \leq \gamma$ . Let G' be obtained from H by deleting a vertex of degree  $\leq \gamma$ . Then |G'| < |H| and G' satisfies 1.1, which is a contradiction. To see this, check:

$$|G'| = |H| - 1 \ge 2k$$
, by Claim 1, and  $|E(G')| \ge |E(H)| - \gamma > \gamma(|H| - k - 1)$ , as  $H$  satisfies 1.1  $= \gamma(|G'| - k)$ .

Hence  $S(H) > \gamma$ . It follows that  $|H| \ge \gamma$ . Thus,

$$\frac{|E(H)|}{|H|} > \frac{\gamma(|H| - k)}{|H|}.$$
 (as  $H$  satisfies 1.1)

Claim 3. H is (k+1)-connected.

**Proof.** By Claim 1,  $|H| \ge 2k + 1 \ge k + 2$  as  $k \ge 1$ . So H is large enough. For a contradiction, suppose that H is not (k+1)-connected. Then H has a proper separation  $\{U_1, U_2\}$  of order at most k.

Let  $H_i = H[U_i]$  for i = 1, 2. Since any vertex  $v \in U_1 - U_2$  has  $d_H(v) \ge S(H) > \gamma$  (by Claim 2), and all neighbours of v in H belong to  $H_1$ , we have  $|H_1| \ge \gamma \ge 2k$ . Similarly,  $|H_2| \ge 2k$ . By minimality of H, neither  $H_1$  nor  $H_2$  satisfies 1.1. Hence  $|E(H_i)| \le \gamma(|H_i| - k)$  for i = 1, 2. But then

$$|E(H)| \le |E(H_1)| + |E(H_2)|$$

$$\le \gamma(|H_1| + |H_2| - 2k)$$

$$\le \gamma(|H| - k),$$
 (by inclusion-exclusion)

since  $|U_1 \cup U_2| \le k$ . This contradicts 1.1 for H. So H is (k+1)-connected, completing the proof of Claim 3 and of the theorem.

#### 1.5 Trees and Forests

A graph with no cycles is a **forest** (also called an acyclic graph). A connected graph with no cycles is a **tree**.

**Theorem 1.5.1.** The following are equivalent for a graph T:

- (i) T is a tree;
- (ii) Any two vertices of T are linked by a unique path in T;
- (iii) T is minimally connected: that is, T is connected but T-e is disconnected for every  $e \in E(T)$ ;

(iv) T is maximally acyclic: that is, T is acyclic but T + xy has a cycle for any two nonadjacent vertices x, y in T.

Corollary 1.5.2. If G is connected then G has a spanning tree.

Corollary 1.5.3. The vertices of a tree can be labelled as  $v_1, \ldots, v_n$  so that for  $i \geq 2$ , vertex  $v_i$  has a unique neighbour in  $\{v_1, \ldots, v_{i-1}\}$ .

**Proof.** We use the labelling from Proposition 1.4.1. This labels the vertices of a given tree G as  $v_1, \ldots, v_n$  such that  $G[v_1, \ldots, v_n]$  is connected. Let  $i \geq 1$  then  $G[v_1, \ldots, v_i]$  is a tree. Note  $G[v_1, \ldots, v_{i+1}]$  is connected by Proposition 1.4.1, so  $v_{i+1}$  has at least one neighbour in  $G[v_1, \ldots, v_i]$ . For a contradiction, suppose that  $v_{i+1}$  has two neighbours z and w in  $G[v_1, \ldots, v_i]$ . There is a (unique)

For a contradiction, suppose that  $v_{i+1}$  has two neighbours z and w in  $G[v_1, \ldots, v_i]$ . There is a (unique) path P in  $G[v_1, \ldots, v_i]$  between z and w, and this path does not visit  $v_{i+1}$ . Hence  $P \cup \{zv_{i+1}, wv_{i+1}\}$  is a cycle in G, contradiction.

Corollary 1.5.4. A connected graph with n vertices is a tree if and only if it has n-1 edges.

**Proof.** Suppose that G is a tree on n vertices. The result is true when n = 1. Now suppose the result is true when n = k. Let G be a tree on k + 1 vertices. Let G be a leaf in G (e.g. take an end vertex of a longest path in G.) Then G - v is a tree on K vertices, so G - v has K - 1 edges (inductive hypothesis). Therefore G has K edges as K has degree 1. This concluses the proof, by induction.

Conversely, suppose that G is connected with n vertices and n-1 edges. Then G contains a spanning tree H, by an earlier corollary. Then H has exactly n-1 edges, since it is a tree on n vertices. Hence H=G, so G is a tree.

Corollary 1.5.5. If T is a tree and G is any graph with  $\delta(G) \geq |T| - 1$  then G has a subgraph isomorphic to T.

## Matchings and Hamilton Cycles

Two edges in a graph are called **independent** if they have no vertices in common. A set M of pairwise independent edges in a graph is called a **matching**.

Given G = (V, E) and  $U \subseteq V$ , say that  $M \subseteq E$  is a **matching of U** if M is matching and every vertex in U is incident with an edge of M. We say that the vertices in U are matched by M, and t hat the vertices not incident with any edge of M are **unmatched**.

A matching M is a **maximal matching** of G if  $M \cup \{e\}$  is not a matching for any  $e \in E - M$ . A **maximum matching** of G is a matching of G such that no set of edges with size greater than |M| is

A maximum matching of G is a matching of G such that no set of edges with size greater than |M| is a matching.

A **perfect matching** of G is a matching of G which matches every vertex of G. Note: a perfect matching is a 1-regular spanning subgraph of G also called a **1-factor** of G.

A k-factor is a k-regular spanning subgraph. A **2-factor** in a graph is the union of disjoint cycles which covers all the vertices.

#### 2.1 Matchings in Bipartite Graphs

Let G = (V, E) be a bipartite graph with vertex bipartition  $V = A \cup B$ . Here A, B are nonempty disjoint sets. We use the convention that all vertices called  $a, a', a'', \ldots$  belong to A and similarly for B.

Let M be matching in G. A path in G which starts at an *unmatched* vertex of A and contains, alternately, edges from E-M and from M, is called an **alternating path** with respect to M.

If an alternating path P ends in an unmatched vertex of B then it is called an **augmenting path**.

**Definition 2.1.1.** A set  $U \subseteq V$  is a **cover** (or **vertex cover**) of G if every edge of G is incident with a vertex in U.

**Theorem 2.1.2** (König, 1931). Let G be a bipartite graph. The size of a maximum matching in G is equal to the size of the minimum vertex cover of G.

**Proof.** Let  $\hat{U}$  be a cover in G and let M be a maximum matching. Then  $|\hat{U}| \geq |M|$  as we must cover every edge of M. Hence it suffices to construct a cover U of G with |U| = |M|.

We build U be choosing one vertex from each edge of M to place into U, as follows:

• If  $ab \in M$  and some alternating path in G with respect to M ends in b. Then put b into U otherwise put a into U.

Let  $ab \in E$ . If  $ab \in M$  then  $a \in U$  or  $b \in U$  by definition of U. Now assume  $abb \notin M$ . Since M is maximum, there exists  $a'b' \in M$  with a = a' or b = b'. If a is unmatched in M then b = b' for some  $a'b' \in M$ . Hence ab is an alternating path ending in b = b', so we chose b' to go into U from the edge  $a'b' \in M$ . So the edge ab is covered by U in this case.

Hence we assume that a = a' for some  $a'b' \in M$ . If  $a = a' \in U$  then we are done. Otherwise  $b' \in U$ , so there is an alternating path P ending in b'. Then  $P = a_1b_1a_2b_2...b'$ , and we have three cases:

- (i) P does not include a or b. Then  $Pab = a_1 a_2 \dots b'ab$  is an alternating path in G with respect to M. By maximality of M, b is matched or else we have an augmenting path. Hence  $b \in U$  as b is the chosen vertex from its matching edge.
- (ii) If b is on P before a, or  $b \in P$  and  $a \notin P$ , then  $P = a_1b_1a_2...b...b'$ . Then we let  $P' = a_1b_1...b$ . This is an alternating path ending in b, so finish proof as case above.
- (iii) If a is on P before b, or  $a \in P$  and  $b \notin P$ . Then  $P = a_1b_1 \dots a_rb_r \dots b'$  and we take  $P' = a_1b_1 \dots ab$ . This is an alternating path ending in b, so finish proof as case above.

This proves U is a cover of G and since |U| = |M|, this completes the proof.

For a subset  $S \subseteq A$ , let  $N(S) = \bigcup_{v \in S} N(v)$  be the set of vertices in B which are neighbours of some vertex in S.

**Theorem 2.1.3** (Hall, 1935). Let G be a bipartite graph. Then G contains a matching of A if and only if

$$|N(S)| \ge |S|$$
 for all  $S \subseteq A$ . (2.1)

**Proof.** We have that this condition is necessary. Now suppose that (2.1) holds. For a contradiction, suppose that G has no matching of A. Then König's Theorem (Theorem 2.1.2) says that G has a cover U with |U| < |A|. Suppose that  $U = A' \cup B'$  with  $A' \subseteq A$  and  $B' \subseteq B$ . Then |A'| + |B'| = |U| < |A|, so |B'| < |A| - |A'| = |A - A'|. Since U is a cover, G has no edges from A - A' to B - B'. Hence  $N(A - A') \subseteq B'$ , and so  $|N(A - A')| \le |B'| < |A - A'|$ . This contradicts Hall's condition 2.1 for S = A - A'. Hence G contains a matching of A.

Corollary 2.1.4. Let G be a bipartite graph and  $d \in \mathbb{N}$ . If  $|N(S)| \ge |S| - d$  for all  $S \subseteq A$  then G has a matching of size |A| - d.

**Proof.** Add d new vertices to B and join each of them by an edge to each vertex of A. Then for all  $S \subseteq A$ , in the new graph G',  $|N_{G'}(S)| \ge |S| - d + d = |S|$ . Hall's condition is satisfied in G'. Therefore there is a matching M in G' which matches all of A. At least |A| - d edges in M are edges of G.

Corollary 2.1.5. If G is a k-regular bipartite graph then G has a perfect matching.

**Proof.** Assume  $k \ge 1$ . Since G is k-regular, |E(G) = k|A| = k|B|, so |A| = |B|. Hence it suffices to prove that G contains a matching of A. Every set  $S \subseteq A$  is joined to N(S) by a total of k|S| edges. These edges are a subset of the k|N(S)| edges incident with |N(S)|. Hence  $k|S| \le k|N(S)|$ 

and diving by k shows that Hall's condition holds. Thus, G has a matching of A.

Corollary 2.1.6. Every regular graph of positive even degree has a 2-factor.

**Proof.** Let G be any 2k-regular graph,  $k \geq 1$ . Without loss of generality, suppose that G is connected (or apply this argument to each component). By Theorem 1.3.1, G has an Euler tour  $v_0v_1 \ldots v_{l-1}v_l$  where  $v_l = v_0, e_i = v_iv_{i+1} \in E(G)$  using each edge exactly once.

Replace each vertex  $v \in V$  with a pair of vertices  $v^-, v^+$ , and replace every edge  $e_i = v_i v_{i+1}$  by the edge  $v_i^+ v_{i+1}^-$ . The resulting graph G' is a k-regular bipartite graph. Hence by Corollary 2.1.5, G' has a perfect matching (1-factor). Collapse every vertex pair  $(v^-, v^+)$  back into a single vertex v, for all  $v \in V$ . The 1-factor of G' becomes a 2-factor of G.

### 2.2 Hamilton Cycles

A **Hamilton cycle** is a connected 2-factor. That is, it is a cycle which includes every vertex.

Say G is **Hamiltonian** if it contains a Hamilton cycle. A Hamiltonian graph G must be connected with minimum degree  $\delta(G) \geq 2$ .

**Theorem 2.2.1** (Dirac, 1952). Every graph with  $n \ge 3$  vertices and with minimum degree at least n/2 has a Hamilton cycle.

**Proof.** Let G be a graph with minimum degree  $\geq n/2$  and  $n \geq 3$  vertices. Then G is connected, as otherwise the degree of any vertex in the smaller component must be < n/2. Let  $P = x_0 \dots x_k$  be a longest path in G. by maximality, all neighbours of  $x_0$  and  $x_k$  lie on P. So at least n/2 of the vertices  $x_0, \dots, x_{k-1}$  are adjacent to  $x_k$  and at least n/2 of these same vertices satisfy  $x_0x_{i+1} \in E(G)$ . By the pigeonhole principle, as k < n, there exists  $i \in \{0, \dots, k-1\}$  with  $x_0x_{i+1}, x_ix_k \in E(G)$ . This gives a cycle  $x_0x_1 \dots x_ix_k \dots x_{i+1}x_0$ . We claim this is a Hamilton cycle. If not then, as G is connected, there is some  $u \notin C$  with a neighbour  $v \in C$ . Then we can start at u, go to v then go around v (in some direction) and stop just before we reach v again (i.e. stop at v and v and v aparts which is longer than v contradiction.

### 2.3 Matchings in General Graphs

Given a graph G, let  $C_G$  be the set of its components and let q(G) denote the number of odd components (connected components having an odd number of vertices).

**Theorem 2.3.1** (Tutte, 1947). A graph G has a perfect matching if and only if

$$q(G-S) \le |S|$$
 for all  $S \subseteq V(G)$ . (2.2)

**Proof.** We have seen that the condition (2.2) is necessary: if G has a perfect matching then (2.2) holds. Now suppose that G has no perfect matching. We want to find a "bad" set  $S_0$  which fails condition (2.2). If |G| is odd then,  $S_0 = \emptyset$  is bad. So assume |G| is even.

**Claim 1.** If G' is obtained from G by adding edges and  $S_0 \subseteq V$  is bad for G' then  $S_0$  is bad for G.

**Proof.** If  $S_0$  bad for G' then  $q(G - S_0) > |S_0|$ . But each odd component of G' - S is a disjoint union of components of G - S, at least one of which must be odd. So  $q(G - S) \ge q(G' - S)$ .

Hence by Claim 1, we can assume that G has no perfect matching but adding any edge to G gives a graph G' which has a perfect matching.

Claim 2. S is a bad set for G if and only if all components of G - S are complete and every vertex in S is adjacent to all other vertices in G.

**Proof.** For proof, call the second half of the claim (\*). If S is bad for G but does satisfy (\*) then we can add an edge to G to get a graph G' with S still bad for G'. This contradicts our assumption on the maximality of G. Conversely suppose S satisfies (\*) but S is not bad. Then we can form a perfect matching since |G| is even. This is a contradiction as G has no perfect matching. Hence S is bad.

Define  $S_0 = \{v \in V : d_G(v) = n - 1\}$  to be the set of all vertices v in G which are adjacent to every other vertex  $w \neq v$ .

#### Claim 3. $S_0$ is bad.

**Proof.** We need to show that  $S_0$  satisfies (\*). For a contradiction, suppose that  $S_0$  does not satisfy (\*). Then  $G - S_0$  has a component K which is not complete. Let  $a, a' \in V(K)$  with  $aa' \notin E(G)$ . Fix a shortest path from a to a' in K which starts  $abc \dots a'$ . Such a path has length  $\geq 2$  and  $ac \notin E(G)$ . Note  $b \in K$ , so  $b \in S_0$ , so there is some  $d \in V$  with  $bd \notin E$ . By maximality of G, there is a perfect matching  $M_1$  in G + ac and a perfect matching  $M_2$  in G + bd. Take a maximal path P in G, starting at d with an edge from  $M_1$ , and taking alternately edges from  $M_1$  and  $M_2$ . Say  $P = d \dots v$ .

- If the last edge of P is in  $M_1$  then v = b or we could extend P. Let C = P + bd (cycle in G + bd).
- If the last edge of P is in  $M_2$  then  $v \in \{a, c\}$  as the  $M_1$  edge incident with v must be ac. Let C be the cycle  $d \dots vbd$ .

In each case, C is an alternating (even length) cycle in G + bd which contains bd. Form  $M'_2$  from  $M_2$  by replacing  $M_2 \cap C$  by  $C - M_2$ . This gives a perfect matching of G, contradiction. Hence  $S_0$  satisfies (\*), so Claim 3 holds and the proof is complete.

Corollary 2.3.2 (Petersen, 1891). Every bridge cubic (3-regular) graph has a perfect matching.

**Proof.** Let G be a bridgeless cubic graph. We prove that G satisfies Tutte's condition. Let  $S \subseteq V(G)$  be given and consider an odd component C of G - S. The sum of the degrees of vertices in C is 3|C|, which is an odd number. Every edge with both end vertices in C contributes an even number to this sum. Hence the number of edges from C to S is odd.

As G has no bridge, there must be at least 3 edges from S to G. Therefore the number of edges from S to G-S is at least 3q(G-S). But the number of edges from S to G-S is bounded above by the sum of the degrees of vertices in S, which is 3|S| as G is cubic. Hence  $3q(G-S) \le \#$  edges from S to  $G-S \le 3|S|$  and thus  $q(G-S) \le |S|$ . Therefore by Tutte's Theorem, G has a perfect matching.

### The Probabilistic Method

This chapter assumes knowledge of elementary probability knowledge. Content from first year is sufficient.

**Example 3.0.1.** Let  $\Omega$  be the set of all graphs on the vertex set  $\{1, 2, ..., n\}$ . Then  $|\Omega| = 2^{\binom{n}{2}}$ . Define  $\pi(G) = 2^{\binom{n}{2}}$  for all  $G \in \Omega$ . This is the *uniform model of random graphs*.

**Lemma 3.0.2.** The expected number of edges in a uniformly chosen graph on the vertex set  $\{1, 2, \dots n\}$  is  $\frac{1}{2} \binom{n}{2}$ .

**Proof.** (From Definition) For  $0 \le m \le \binom{n}{2} = N$ , there  $\binom{N}{m}$  are exactly of graphs on vertex set  $\{1, \ldots, n\}$  with m edges. Let X be the number of edges in the random graph. Then

$$EX = \sum_{m=0}^{N} \Pr(X = m) \cdot m$$

$$= \sum_{m=0}^{N} \frac{\binom{N}{m}}{2^{N}} \cdot m$$

$$= \frac{N}{2^{N}} \sum_{m=1}^{N} \frac{(N-1)!}{(m-1)!(N-m)!}$$

$$= \frac{N}{2^{N}} \sum_{j=0}^{N-1} \binom{N-1}{j}$$

$$= \frac{N}{2^{N}} 2^{N-1}$$

$$= \frac{N}{2} = \frac{1}{2} \binom{n}{2}.$$
(by the binomal theorem)
$$= \frac{N}{2} = \frac{1}{2} \binom{n}{2}.$$

Let  $A \subseteq \Omega$  be an event. The indicator variable  $I_A$  for  $A \subseteq \Omega$  is

$$I_A(z) = \begin{cases} 1 & \text{if } z \in A \\ 0 & \text{otherwise.} \end{cases}$$

**Definition 3.0.3** (Linearity of Expectation). Let  $X_1, \ldots, X_k$  be random variables on  $\Omega$  and let  $c_1, \ldots, c_k \in \mathbb{R}$ . Define the random variable  $X = c_1 X_1 + \cdots + c_k X_k$ . Then

$$\mathbb{E}[X] = c_1 \mathbb{E}[X_1] + c_2 \mathbb{E}[X_2] + \dots + c_k \mathbb{E}[X_k].$$

**Definition 3.0.4** (Markov's Inequality). SUppose that  $X : \Omega \to [0, \infty)$  is a nonnegative random variable on  $\Omega$  and let k > 0. Then

$$\Pr(X \ge k) \le \frac{\mathbb{E}[X]}{k}.$$

In particular, if X is a nonnegative integer-valued random variable then

$$\Pr(X \neq 0) \leq \mathbb{E}[X].$$

Let  $k \geq 2$  be an integer. Events  $A_1, \ldots, A_k$  in  $\Omega$  are **mutually independent** if for all  $j, \ell_1, \ldots, \ell_j$  with  $2 \leq j \leq k$  and  $1 \leq \ell_1 < \ell_2 < \cdots < \ell_j \leq k$ ,

$$\Pr\left(\bigcap_{i=1}^{j} A_{\ell_i}\right) = \prod_{i=1}^{j} \Pr(A_{\ell_i}).$$

**Lemma 3.0.5.** Let  $\Omega$  be the set of all subsets of some given set S, where |S| = n. Define a random set  $X \subseteq S$  by setting  $\Pr(x \in X) = \frac{1}{2}$ , independently for each  $x \in S$ . Then  $\Pr(X = A) = 2^{-n}$  for all  $A \subseteq S$ , so this gives the uniform probability space on  $\Omega$ .

**Proof.** Fix  $A \subseteq \Omega$ . Then

$$\Pr(X = A) = \prod_{x \in A} \Pr(\text{heads}) \cdot \prod_{x \notin A} \Pr(\text{tails})$$
 (using independence)
$$= \left(\frac{1}{2}\right)^{|A|} \cdot \left(\frac{1}{2}\right)^{n-|A|}$$

$$= \left(\frac{1}{2}\right)^{n} = 2^{-n}$$

as claimed.

**Theorem 3.0.6** (Alon & Spencer, Theorem 2.2.1). Let G be a graph with n vertices and m edges. Then G contains a bipartite subgraph with at least m/2 edges.

**Proof.** Let  $\Omega$  be the set of all subsets of V(G). Then  $|\Omega| = 2^n$ . Consider the uniform probability space on  $\Omega$ . Let  $A \subseteq V$  be a randomly chosen element of  $\Omega$  and define B = V - A. Call  $xy \in E(G)$  a crossing edge if exactly one of x, y belongs to A. Let X be the number of crossing edges. Finally, for each edge  $e \in E(G)$  define the indicator variable

$$X_e = \begin{cases} 1 & \text{if } e \text{ is a crossing edge,} \\ 0 & \text{otherwise.} \end{cases}$$

Then  $X = \sum_{e \in E(G)} X_e$ . For any  $e = xy \in E(G)$ , we have,

$$\Pr(x \in A \text{ and } y \notin A) = \Pr(x \in A) \Pr(y \in A)$$
 (using independence)  
=  $\frac{1}{2} \times \frac{1}{2} = \frac{1}{4}$ .

Therefore

$$\mathbb{E}X_e = \Pr((x \in A \text{ and } y \notin A) \text{ or } (x \notin A \text{ and } y \in A))$$

$$= \Pr(x \in A \text{ and } y \notin A) + \Pr(x \notin A \text{ and } y \in A)$$

$$= \frac{1}{4} + \frac{1}{4} = \frac{1}{2}.$$
(events are disjoint)

Hence, by linearity of expectation,

$$\mathbb{E}X = \sum_{e \in E(G)} \mathbb{E}X_e = \frac{m}{2}.$$

Thus there exists a fixed set  $A_0 \subseteq V(G)$  which has at least  $\frac{m}{2}$  crossing edges. The corresponding bipartition  $(A_0, V(G) - A_0)$  defines a bipartite subgraph consisting of the  $\geq \frac{m}{2}$  crossing edges.  $\square$ 

An **independent set** in a graph G is a subset  $U \subseteq V$  such that if  $v, w \in U$  then  $vw \in E(G)$ . Let  $\alpha(G)$  be the size of a maximum independent set in G, called the **independence number**.

**Theorem 3.0.7.** Let G have n vertices and nd/2 edges, where  $d \ge 1$ . Then  $\alpha(G) \ge \frac{n}{25T1d}$ . Note d, is the average degree of G.

**Proof.** Define the random subset  $S \subseteq V(G)$  by  $\Pr(v \in S) = p$ , independently for all  $v \in V$ . Here  $p \in [0,1]$  which we will fix later.

Let X = |S| and let Y be the number of edges of G with both endvertices in S. Then  $\mathbb{E}X = pn$ . For  $e \in E(G)$  let  $Y_e$  be the indicator variable for the event  $e \subseteq S$ . Then for every  $e = xy \in E(G)$ ,

$$\mathbb{E}Y_e = \Pr(x \in S \text{ and } y \in S)$$

$$= \Pr(x \in S) \cdot \Pr(y \in S)$$

$$= p^2.$$
 (by independence)

Therefore, by linearity of expectation and the fact that  $Y = \sum_{e \in E(G)}$  we have

$$\mathbb{E}Y = \sum_{e \in E(G)} \mathbb{E}Y_e = \frac{nd}{2}p^2.$$

By linearity of expectation,

$$\mathbb{E}(X - Y) = \mathbb{E}X - \mathbb{E}Y = pn - p^2 \frac{nd}{2}.$$

Want to choose p to maximise this, so  $p = \frac{1}{d}$  and  $p \in [0,1]$ . Substituting gives  $\mathbb{E}(X - Y) = \frac{n}{2d}$ . Hence there exists a fixed set  $S_0 \subseteq V(G)$  with  $|S_0| - (\# \text{ edges in } S_0) \ge \frac{n}{2d}$ . Delete one vertex from each edge within  $S_0$  to give a set  $S^*$  of at least  $\frac{n}{2d}$  vertices which is an independent set.  $\square$ 

## Graph Colourings

A vertex colouring of a graph G = (V, E) is a function  $c : V \to S$  such that  $c(u) \neq c(v)$  whenever  $uv \in E$ . Here S is the set of available colours, usually  $S = \{1, 2, ..., k\}$  for some positive integer k.

A k-colouring of G is a colouring  $c: V \to \{1, 2, ..., k\}$ . Often we want the smallest value of k for which a k-colouring of G exists. This smallest value of k is called the chromatic number of G, denoted  $\chi(G)$ .

If  $\chi(G) = k$  then G is said to be k-chromatic. If  $\chi(G) \leq k$  then G is said to be k-colourable.

The set of all vertices in G with a given colour under c is called a colour class. Each colour class is an independent set. k-colouring is a partition of V(G) into k independent sets.

A clique in a graph G is a complete subgraph of G. The order of the largest clique in G is called the clique number of G, denoted  $\omega(G)$ .

Fact:  $\chi(G) \ge \omega(G)$  and  $\chi(G) \ge n/\alpha(G)$ .
